A growing number of people accepted to join the so-called internet-of-things scenario

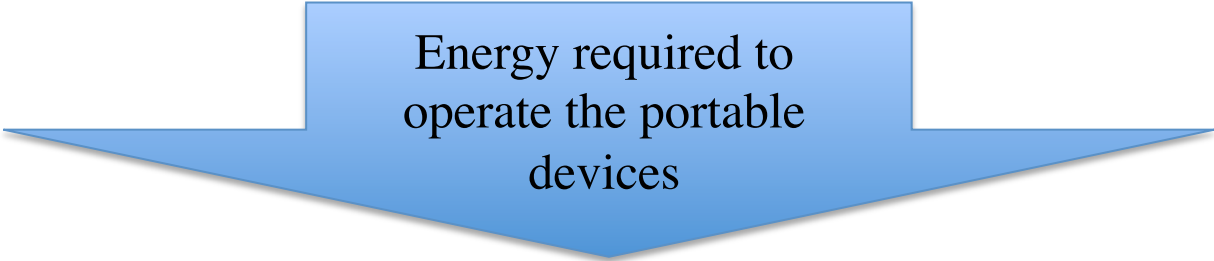

Source: Cisco IBSG, April 2011

Before this scenario becomes a reality the device powering issue needs to be addressed and solved.

The challenge of efficient management of energy is a key aspect to consider in computing systems, especially for applications in smart sensors and Internet of Things devices.

European Commission **Workshop** on "Energy-Efficient Computing Systems, dynamic adaptation of Quality of Service and approximate computing". Nov. 27 2014 - Brussels

Energy required to
operate the portable
devices

We need to bridge the gap by acting on both arrows

Energy available from
portable sources

Some modeling

The device powering issue: 1) How much energy is needed to power a device ?
2) Where does the device get the needed energy ?

We consider devices at MEMS scale and below

We consider “ICT devices”: i.e. devices mainly devoted to computing task

An **ICT device** is an info-thermal machine that inputs **information** and **energy** (under the form of work), processes both and outputs information and energy (mostly under the form of heat).

Some interesting questions:

Why all the energy ends up in heat? What does it mean “energy dissipation”? Can be avoided?

What is the role of information? Is this a physical quantity that affects the energy transformations?

We need a physical model...

Two physical systems:

They transform energy

They have many d.o.f. (presence of fluctuations)

They are operated in a changing environment

~~Thermodynamics~~

~~Statistical mechanics~~

Non-equilibrium statistical mechanics

In this framework we can describe the device behavior in terms of few relevant d.o.f. via a procedure called “adiabatic elimination” or “coarse graining approach”: we exchange the dynamics of a *not small isolated system* with *small not isolated system*.

Let's see an example...

Example: physical system pendulum

Focus on the pendulum angle

If we come back after a while..

Mass $m = 1 \text{ Kg}$, Length $l = 1 \text{ m}$, rms motion = $2 \cdot 10^{-11} \text{ m}$

How to model such a behavior?

Motion equation for the angle variable:

$$m l^2 \ddot{\theta} + mgl \sin \theta = 0$$

This is clearly an approximation that does not describe the whole phenomena:

- 1) Amplitude decay is missing
- 2) Zero amplitude fluctuation is missing

Improved motion equation for the angle variable $m l^2 \ddot{\theta} - \gamma \dot{\theta} + mgl \sin \theta + \zeta(t) = 0$

They come from the neglected N-1 d.o.f.

$$\langle \zeta(t) \zeta(0) \rangle = 2 K_B T \gamma \delta(t)$$

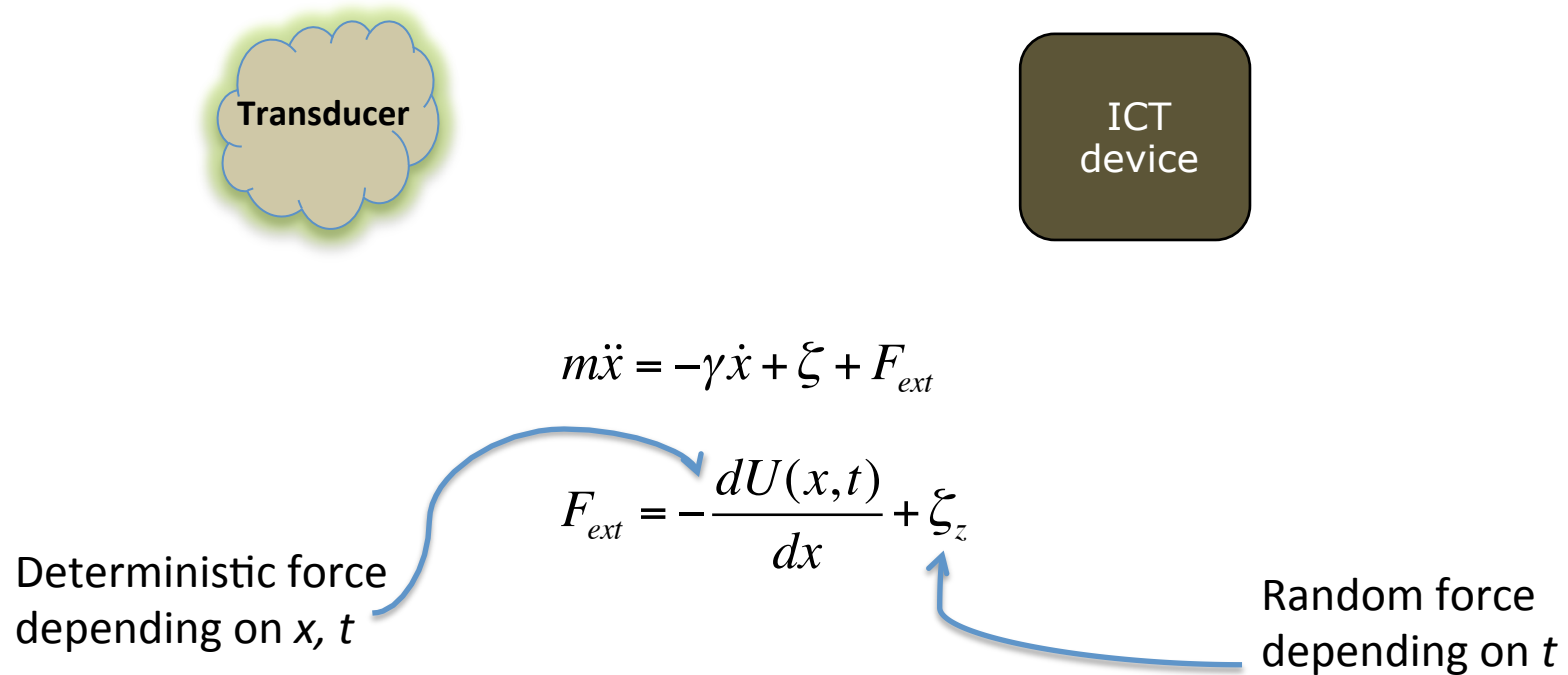

The viscous drag expression can be generalized in order to describe a wider class of damping functions

$$-\int_{-\infty}^t \gamma(t - \tau) \dot{x} d\tau \quad \longrightarrow \quad \langle \zeta(t) \zeta(0) \rangle = kT \gamma(|t|)$$

Fluctuation – Dissipation theorem

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

If $F_{ext} \gg \zeta$ then the thermal noise contribution can be ignored

$$m\ddot{x} = -\frac{dU(x,t)}{dx} - \gamma\dot{x} + \zeta_z$$

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

ICT
device

(example from vibration harvester)

$$m\ddot{x} = -\frac{dU(x)}{dx} - \gamma\dot{x} - c(x, V) + \zeta_z + \zeta$$

$$\dot{V} = F(\dot{x}, V)$$

$$\langle \zeta(t) \zeta(0) \rangle = 2 K_B T \gamma \delta(t)$$

See e.g. Halvorsen, E. Energy Harvesters Driven by Broadband Random Vibrations, *Microelectromechanical Systems, Journal of* (Volume:17 , Issue: 5), 2008.

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

(example from a digital binary switch)

$$m\ddot{x} = -\frac{dU(x)}{dx} - \gamma\dot{x} + F_{sw} + \zeta$$

$\langle \zeta(t) \zeta(0) \rangle = 2 K_B T \gamma \delta(t)$

Langevin equation approach

$$m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \gamma\dot{x} + \xi$$

This is a stochastic dynamics whose solution $x(t)$ appears like

Probability density $P(x,t)$.

$P(x,t)dx$ represents the probability for the observable x to be in $(x, x+dx)$.

$P(x,t)$ is a deterministic quantity and its time evolution of can be described in terms of the associated Fokker-Planck equation.

Some considerations

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

An **ICT device** is an info-thermal machine that inputs **information** and **energy** (under the form of work), processes both and outputs information and energy (mostly under the form of heat).

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

Clearly this energy is obtained from the ambient...

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

Energy is conserved....

$$E_e = E_i - C$$

Question: can we make $C = 0$?

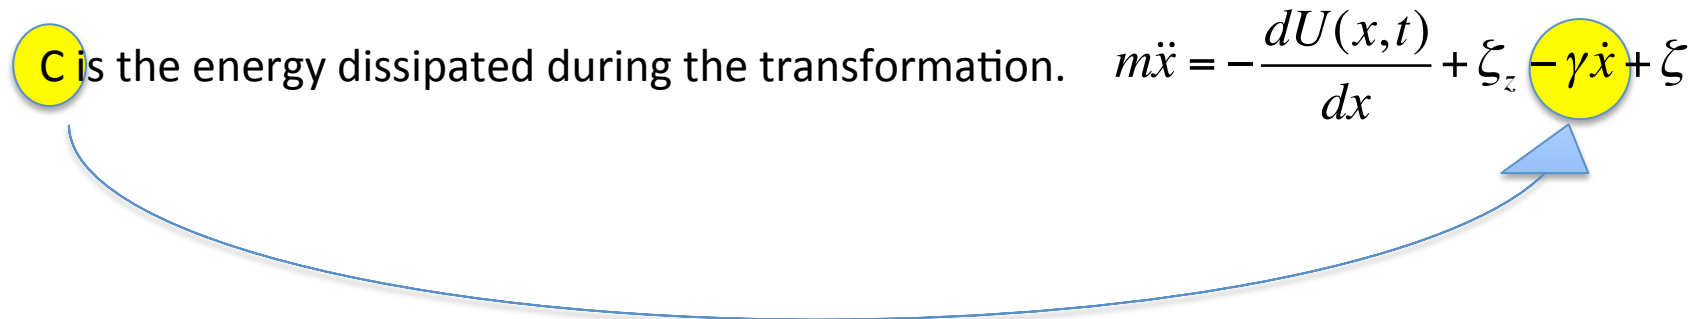

C is the energy dissipated during the transformation. $m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \gamma\dot{x} + \zeta$

$C=C(\gamma)$ and γ is associated with the relaxation to equilibrium and depends on the characteristics of the device/material.

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

C is the energy dissipated during the transformation. $m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \gamma\dot{x} + \zeta$

The usual solution is to go very slow, i.e. to minimize \dot{x}

Good news: In principle there is no physical law that forbids to make $C = 0$

Bad news: This affects the power we can use in the device

$C=C(\gamma)$ can be a function of time and change with the dissipation process.
Viscous damping, thermo-elastic damping, structural damping, ...

Generalized Langevin equation $m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \int_{-\infty}^t \gamma(t-\tau) \dot{x} d\tau + \zeta$

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

$$m\ddot{x} = -\frac{dU(x,t)}{dx} + \xi_z - \gamma\dot{x} + \xi$$

Finally, the role of the potential energy $U(x,t)$

linear oscillator approach

$$U(x) = \frac{1}{2}ax^2$$

Left: configuration for harvesting vertical vibrations.
Right: configuration for harvesting horizontal vibrations.

Linear systems

When $U(x) = \frac{1}{2} kx^2$ it is called a **linear system**

Linear systems have some interesting features... (and engineers like them most)

- 1) There exist a simple math theory to solve the eq.s
- 2) They have a resonant behaviour (resonance freq.)
- 3) They can be “easily” realized with catilevers and pendula

Transfer Function $H(\omega)$

In the spectral domain, for a linear system, is always possible to write its response to an external force like: $X(\omega) = H(\omega)F(\omega)$

Where H is the system transfer function.

$$H(\omega) = H'(\omega) + i H''(\omega) = |H(\omega)| e^{i\phi(\omega)}$$

Vibrations energy harvesting

Linear systems

In a linear system, thanks to the transfer function $H(\omega)$, the output spectrum can be obtained from the input spectrum through a simple multiplication...

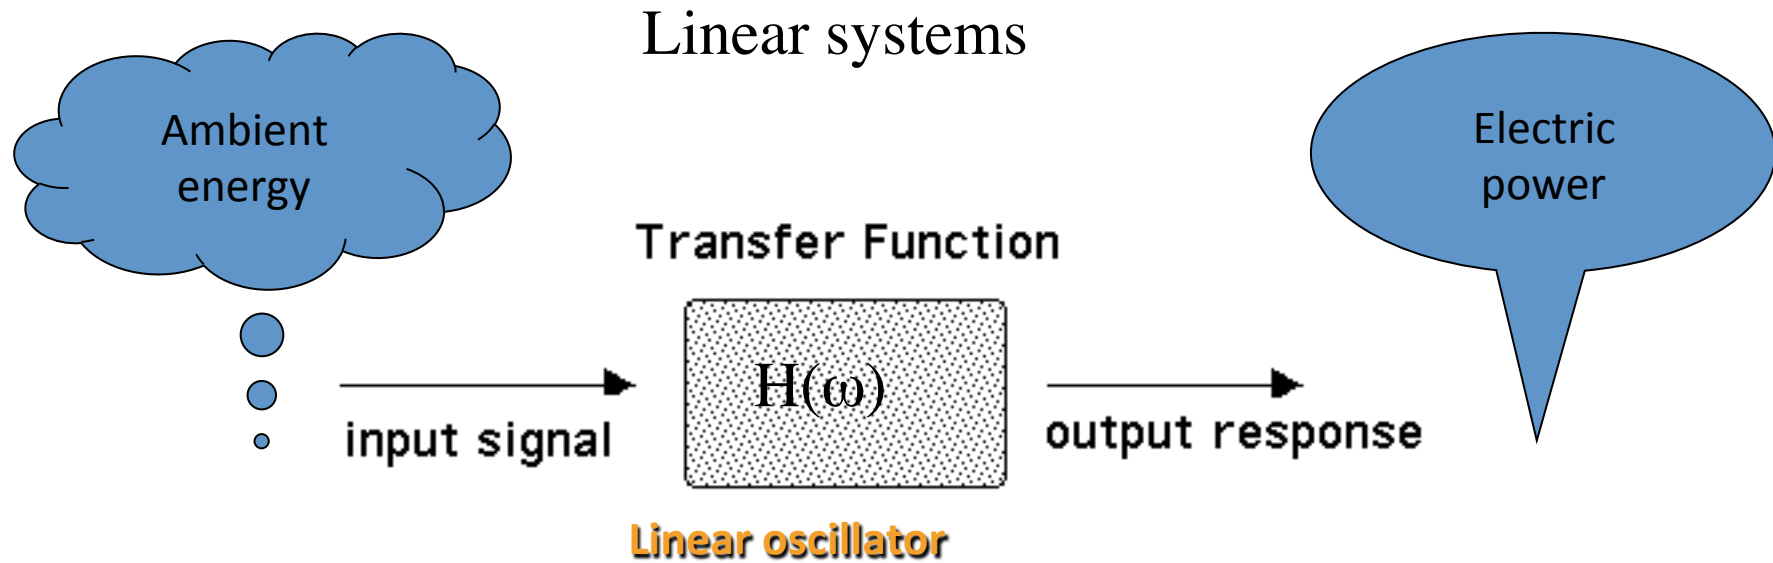

$$S_x(\omega) = |H(\omega)|^2 S_z(\omega)$$

Output power spectrum

Input power spectrum

Vibrations energy harvesting

The transfer function is a math function of the frequency, in the complex domain, that can be used to represent the performance of a linear system

For a linear system the transfer function presents one or more peaks corresponding to the resonance frequencies and **thus it is efficient mainly when the incoming energy is abundant in that regions...**

Linear systems

The transfer function is important because it acts as a filter on the incoming energy...

Freq. spectrum of
the available
energy

Welcome to the Real Vibrations web site.

What is Real Vibrations ?

This web site is home to a digital database containing numerical time series and spectral representations of experimentally acquired vibration signals. Most importantly, Real Vibrations is a participatory research project that aims at creating the world largest repository of vibrations recorded from everyday life objects and people movements.

Cars, trains, airplanes, and even human beings, constantly vibrate and these vibrations can be recorded with various devices and stored in such a way that they are readily available and easily usable both by researchers and non expert visitors.

What are these data for?

A database of vibration data is a map of the moving world. To many this is of no meaning and little use. To us this is a map of potentially useful energy. In fact vibrations can be efficiently transformed in electrical energy that can be employed to power electronic devices such as wireless sensors: a way to improve the microelectronic world and make a better use of energy. In a near future we believe that this micro-generators that transform vibrations into electric energy will be able to integrate and/or substitute the existing batteries for a better and healthier planet.

How to take part in the project ?

If you are a scientist or a professional in the energy world, please contact the NiPS Laboratory at the Department of Physics, University of Perugia in order to become a professional partner of the Real Vibrations project.

If you are a student and/or a volunteer you can still contribute to this project simply by acquiring vibration data with your smartphone and uploading them to the database.

Please find the iPhone app [here](#).

Nanopower

Vibrations energy harvesting

Linear systems

For a linear system the transfer function presents one or more peaks corresponding to the resonance frequencies and thus it is efficient mainly when the incoming energy is abundant in that regions...

This is a serious limitation when you want to build a small energy harvesting system...

Limitations of linear energy harvesters

$$S_y(\omega) = |H(\omega)|^2 S_x(\omega)$$

- Transfer function: one or more peaks corresponding to the resonance frequencies
- Difficult, if not impossible, to build small low-frequency resonant systems
- The frequency spectrum of available vibrations not sharply peaked.

Vibrations energy harvesting

Whish list for the perfect vibration harvester

- 1) Capable of harvesting energy on a broad-band
- 2) No need for frequency tuning
- 3) Capable of harvesting energy at low frequency

- 1) Non-resonant system
- 2) “Transfer function” with wide frequency resp.
- 3) Low frequency operated

Vibrations energy harvesting

$$\left\{ \begin{array}{l} m\ddot{x} = -\frac{dU(x)}{dx} + \gamma\dot{x} - K_V V + \zeta_z \\ \dot{V} = K_c \dot{x} - \frac{1}{\tau_p} V \end{array} \right.$$

The oscillator dynamics

$U(x)$ Represents the Energy stored

$$U(x) \neq \frac{1}{2}kx^2$$

NON-Linear mechanical oscillators

- 1) Non-resonant system
- 2) “Transfer function” with wide frequency resp.
- 3) Low frequency operated

The future of powering for small mobile electronic devices

Present solution: - ~~disposable batteries~~
- rechargeable batteries **energy storage issue**

Future solution: - energy harvesting + storage

Take-home message:

- 1) Focusing **only** on energy harvesting produces misconception. The focus should be on energy transformation processes.
- 2) Both ends of the gap should be addressed if we want to move from labs to market.

What future for the subject of **energy harvesting / autonomous devices** ?

Bright!

The problem of powering small (and not so-small) autonomous devices has been already addressed and solved by nature. There is plenty of devices that process information (and actuate) while transforming energy from low entropy sources into heat.

None of them carries disposable batteries !
